

# ***COVID-19 related effects on early language development***

**Sónia Frota, Jovana Pejović, Cátia Severino & Marina Vigário**

University of Lisbon, Center of Linguistics

# Introduction

- Language includes auditory and visual cues relevant to language learning

e.g., Kuhl, 2014; Lewkowicz and Hansen-Tift, 2012; Sebastián-Gallés et al., 2012; Tomalski et al., 2013; Tsang et al., 2018; Choi et al., 2018; Morin-Lessard et al., 2019; Pejovic et al., 2019; Pons et al., 2019; Cruz et al., 2020; Sekiyama et al., 2021

# Introduction

- **COVID-19**

Affect early  
speech  
processing!

Effects on  
language  
development,  
cognitive  
development

e.g., Davies et al., 2021; Deoni et al., 2021; Kartushina et al., 2022

---

# Introduction

- **Developmental research needs to understand whether and when these potential effects take place in early development**
- **This longitudinal study addresses this question**
  1. Comparing **word segmentation abilities** in **7-9-month-old** infants born during the pandemic (in presence or not of a face mask) with earlier segmentation data collected in 2016-2017 (Butler & Frota, 2018)
  2. Examining their **later** language development (between **12 and 24 months** of age) in a series of follow up studies

# Study timeline

May  
2020

March  
2022

**Pandemic**

Obligatory mask use (all public places, nurseries included) + other COVID-19 related restrictions

June 2021  
**DATA COLLECTION SEGMENTATION STUDY**  
Dec 2021

Nov 2021

12 mos

STILL WITHIN THE HIGHLY RESTRICTED PERIOD

FOLLOW UP  
STUDIES

1 TO 3 MONTHS AFTER

18 mos

4 TO 7 MONTHS AFTER

May 2023

24 mos

10 TO 13 MONTHS AFTER

# 1. Word segmentation

édifícilencontrarumapalavranestafrase

CHALLENGE!

- **Word segmentation: crucial milestone for language development** (Singh et al., 2012; Bergmann and Cristia, 2016; Kidd et al., 2018; Hoareau et al., 2019, Frota et al., 2020).
- **It might be supported by audiovisual information** (de la Cruz-Pavía et al., 2019; Tan and Burnham, 2019)

# 1. Word segmentation: COVID-19 study

## Summary

1. COVID-19 related changes hinder early word segmentation abilities
  - Presence/absence of the face mask
  - No segmentation was found at 7-9 months, not even at the prosodic edge
2. Effect of continued exposure to altered speech cues together with (other) COVID-related changes > Difference between pre-pandemic data and the data collected during the pandemic

**Auditory Experiment (AUD)**

**Audiovisual Experiment (AV)**

WITHOUT

WITH

7–9-month-old infants

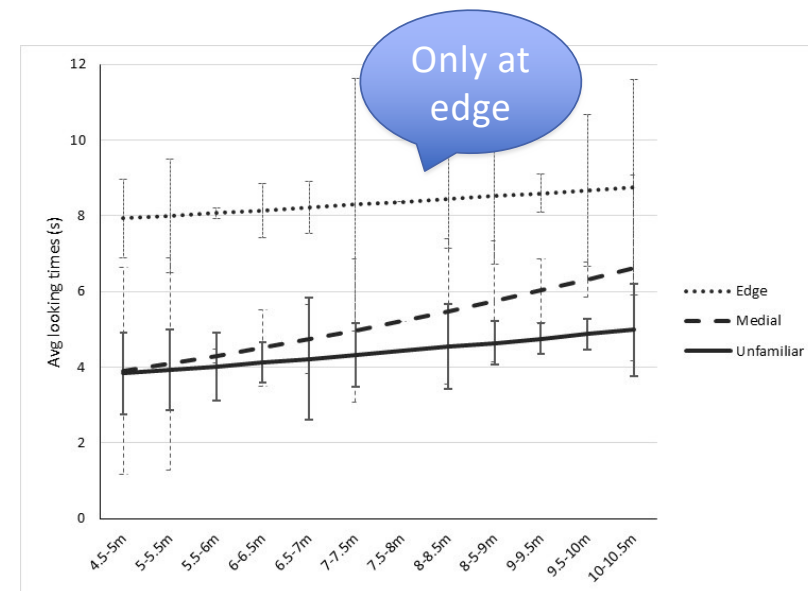

✓ Segmentation at prosodic edge

# 1. Word segmentation: COVID-19 study

## ■ Followed Butler & Frota (2018), B&F

- Emerging word segmentation abilities in European Portuguese learning infants from 4 to 10 months of age
- Auditory task using a visual familiarization paradigm

Butler & Frota (2018) *Journal of Child Language*

## Method- Participants

- 77 infants from monolingual EP homes recruited in the Lisbon area

Full-term, no familial risks for language impairment, no health-related issues

Face mask exposure (in-lab) questionnaire, language exposure parental questionnaire (Molnar et al., 2014), EP-CDI short form, CSBS checklist

### **Auditory Experiment (AUD): 37 infants**

- With-mask condition: 18 infants (mean age, 8.4 months; range, 7 months, 17 days – 9 months, 22 days; 10 females)
- Without-mask condition: 19 infants (mean age, 8.5 months, range, 7 months, 5 days – 9 months, 7 days; 8 females)

No differences in age, mask exposure, nº of people infant interacted with, CDI, or CSBS

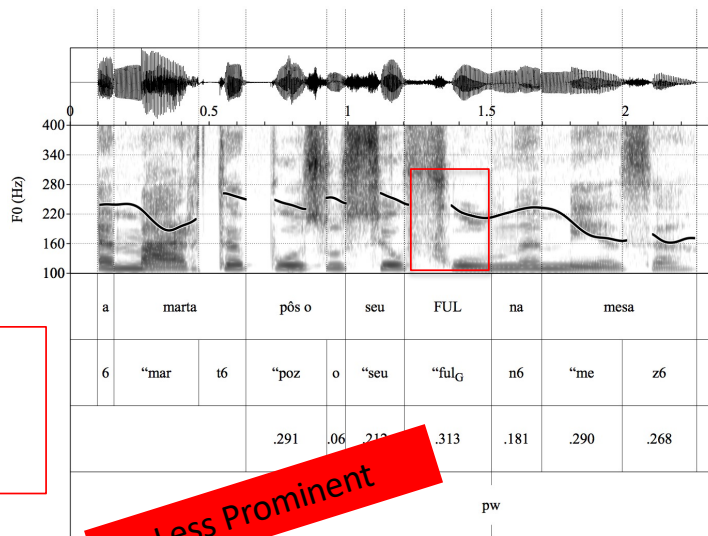

### **Audiovisual Experiment (AV): 40 infants**

- With-mask condition: 20 infants (mean age, 8.1 months; range, 7 months, 4 days to 9 months, 7 days; 9 females)
- Without-mask condition: 20 infants (mean age, 8.2 months, range, 7 months, 6 days to 9 months, 11 days; 8 females)

No differences in age, mask exposure, nº of people infant interacted with, CDI, or CSBS

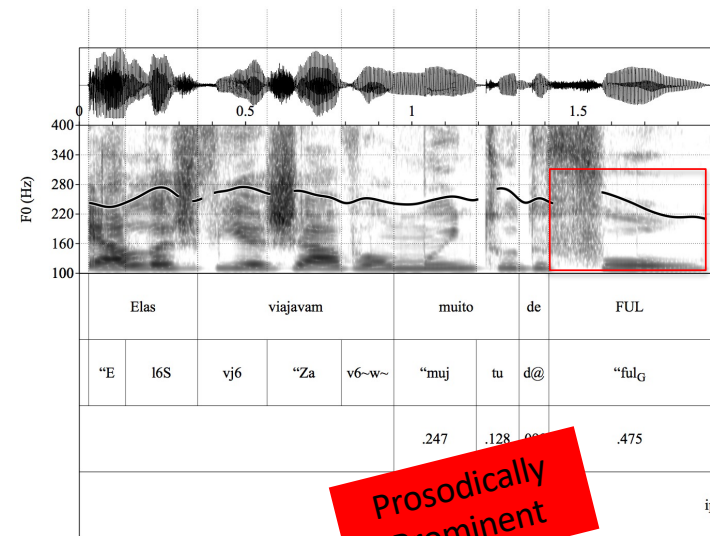

# Method - Materials

- Materials (= B&F, 2018 + Mask condition, recorded by the same female speaker):
  - 4 monosyllabic pseudo words (CVC/CVG)
  - 2 passages constructed for each word, one for **medial** and one for **edge** condition

Less Prominent

Internal to the Intonational Phrase (IP)

Prosodically Prominent

Final Intonational Phrase edge (=sentence)

## Method- Materials

- **Audiovisual Experiment (AV):** Audiovisual stimuli

Video recordings (professional JVC camera, model GY-HM11E, in .mov format, a 4:3 aspect ratio, 25 fps) occurring simultaneously with the recordings of the auditory stimuli.

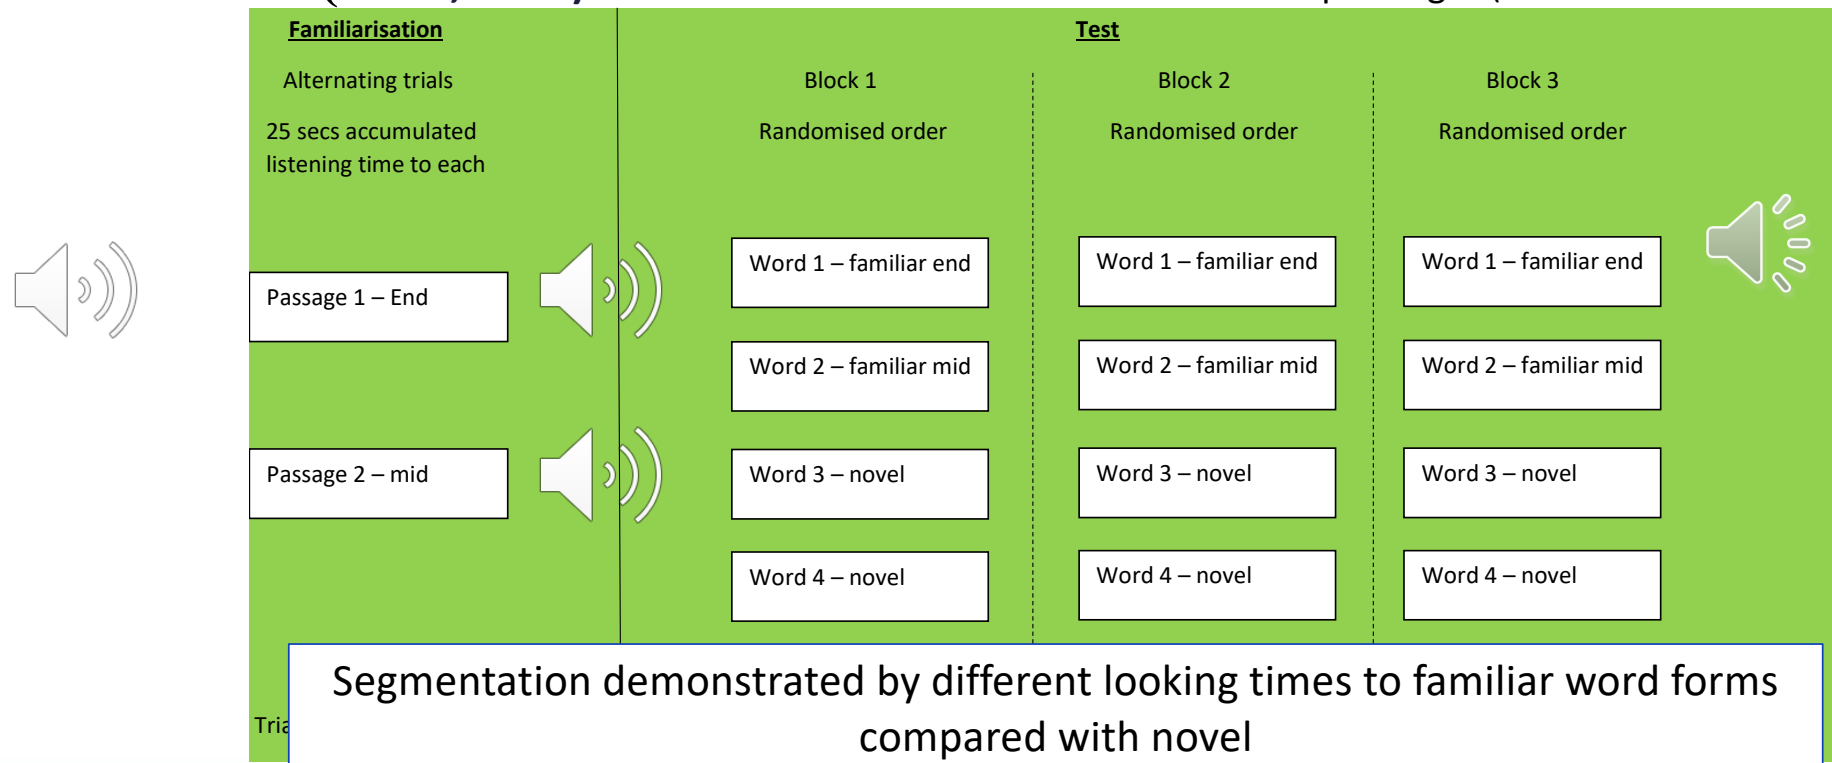

The speaker was instructed to speak in an infant-friendly manner. No other instructions were given.

# Method - Procedure

Familiarized with passages; Tested with words

**Procedure (= B&F, 2018):** Modified version of the visual habituation paradigm (Altvater-Mackensen & Mani, 2013)

## Method - Procedure

### ▪ **Audiovisual Experiment (AV):**

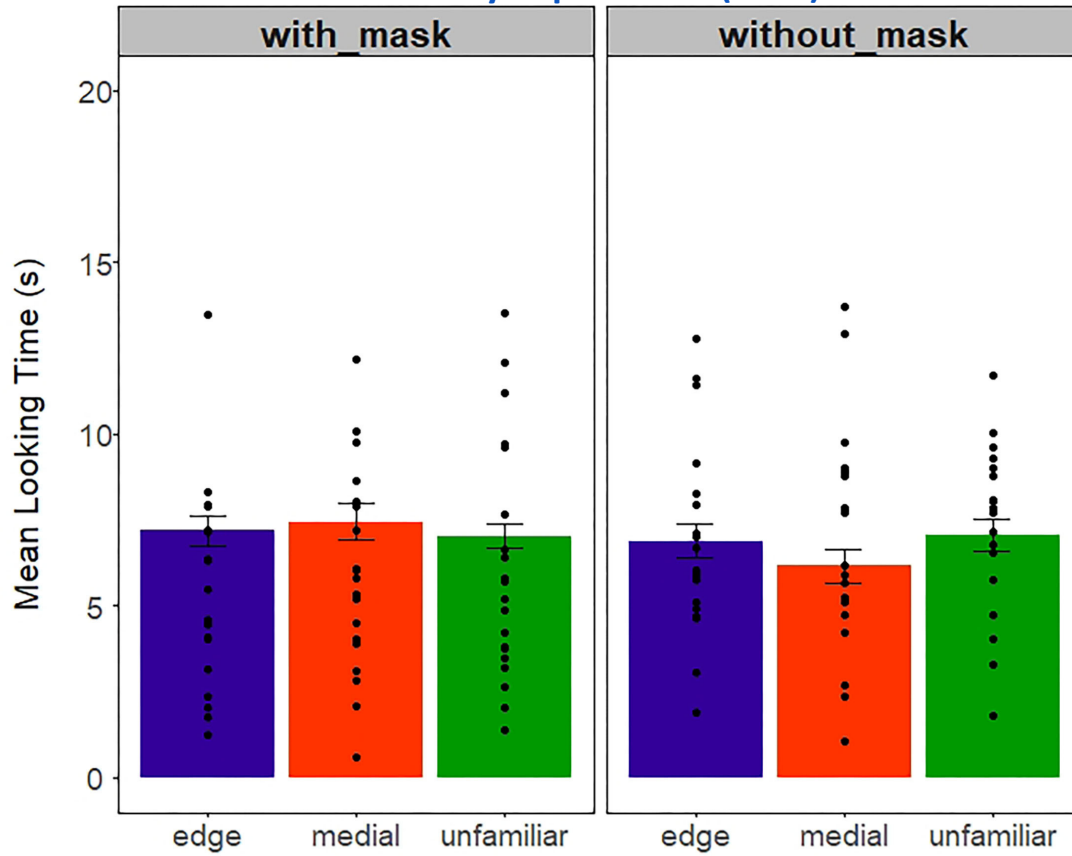

Same procedure as in the Auditory experiment, except that  
- **stimuli in the familiarization phase were audiovisually presented**

Infants' looking data were collected  
using an EyeLink 1000 Plus eye tracker

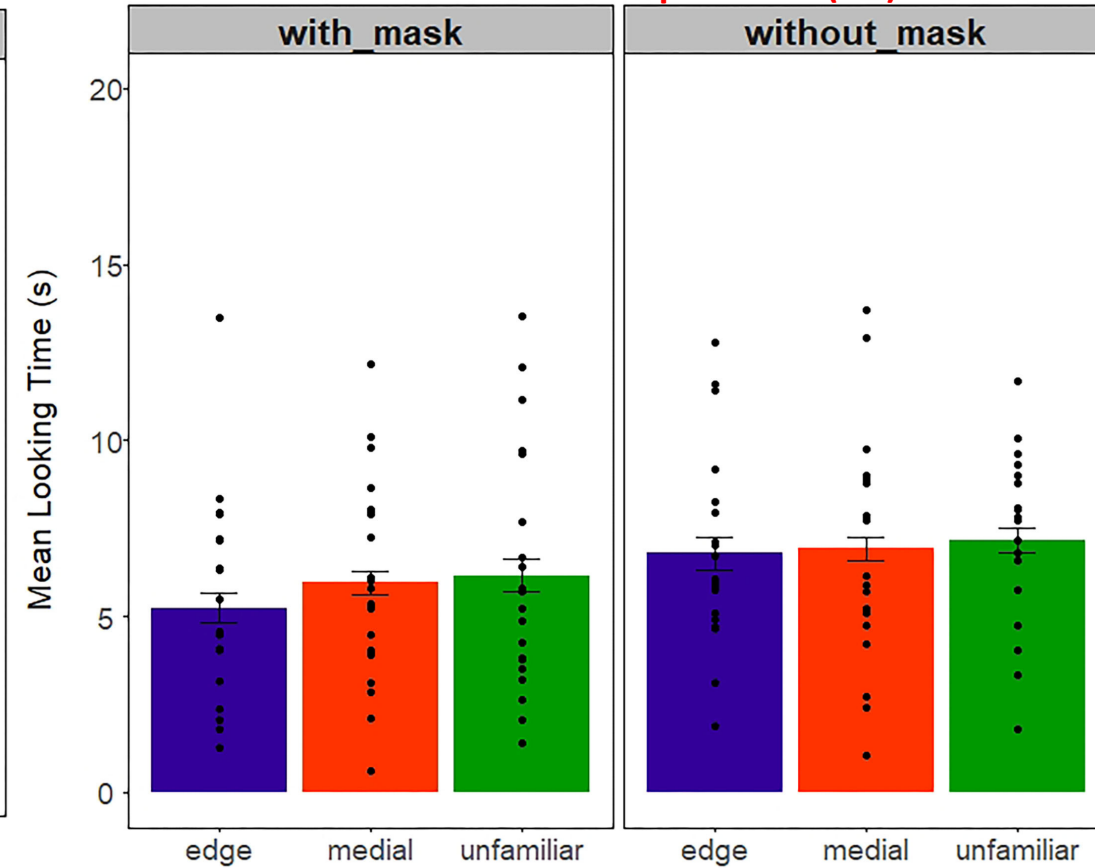

# Results

**Auditory Experiment (AUD)**

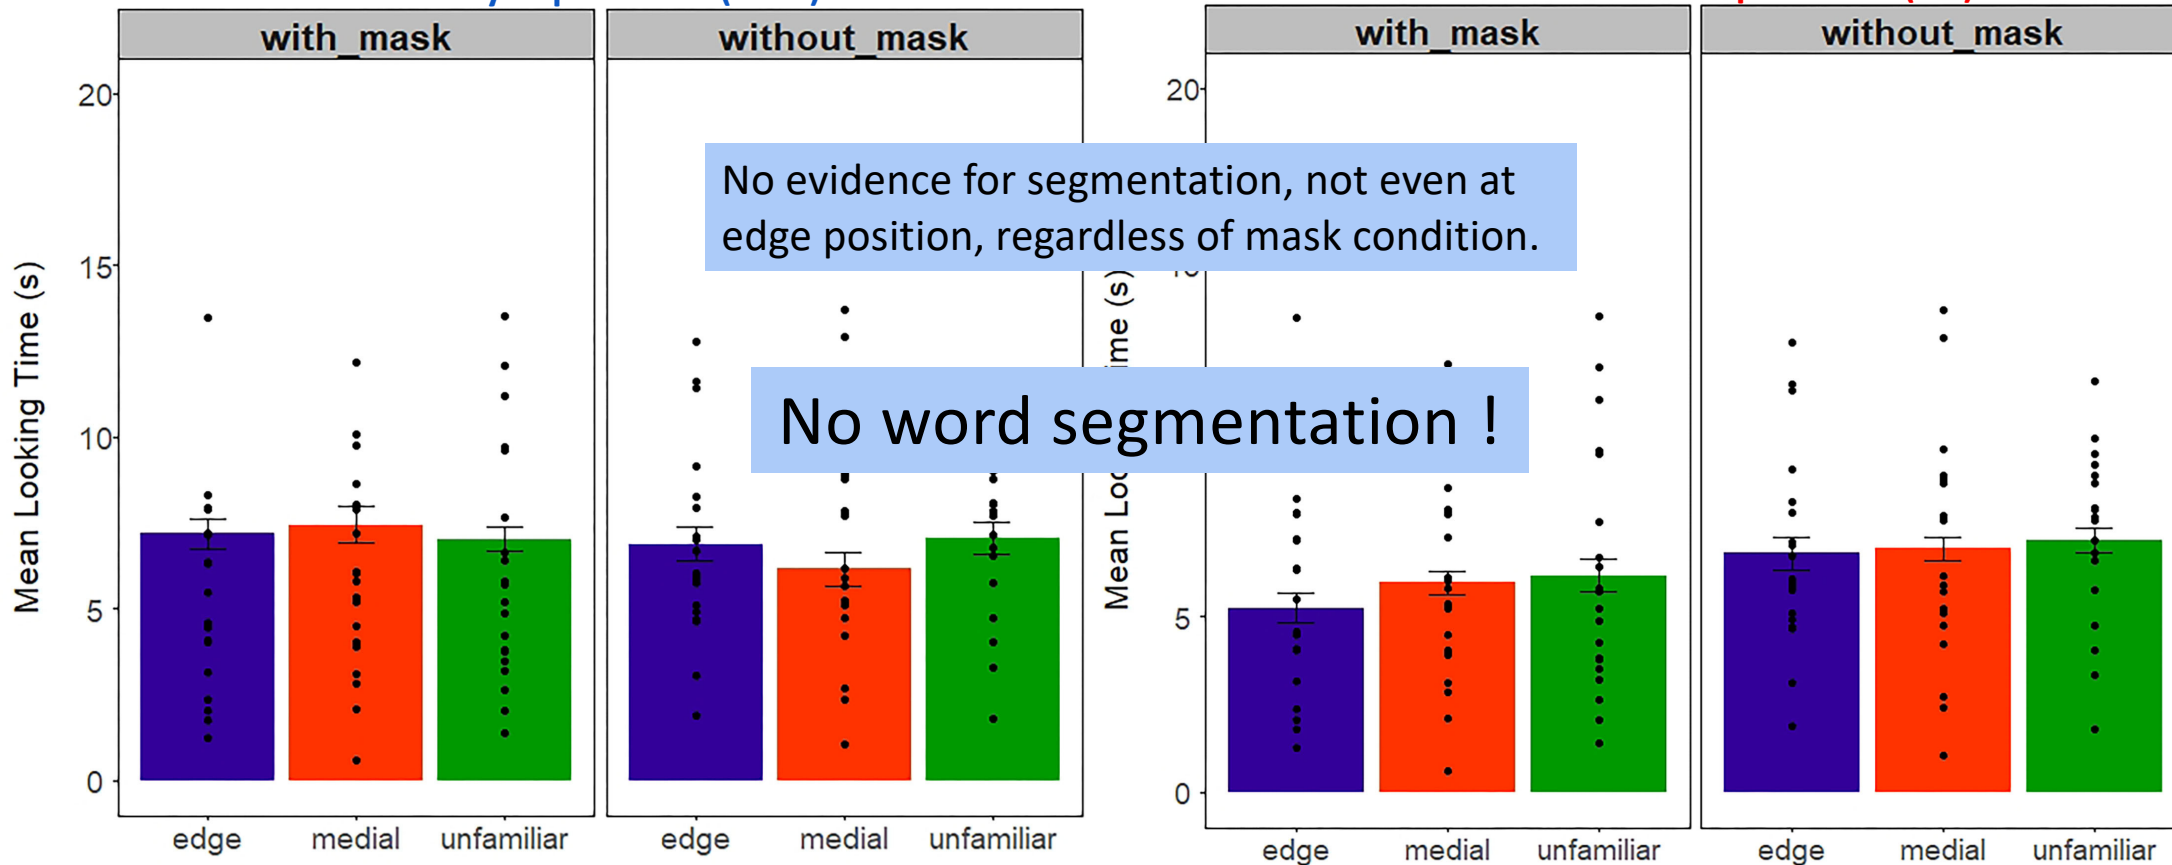

**Audiovisual Experiment (AV)**

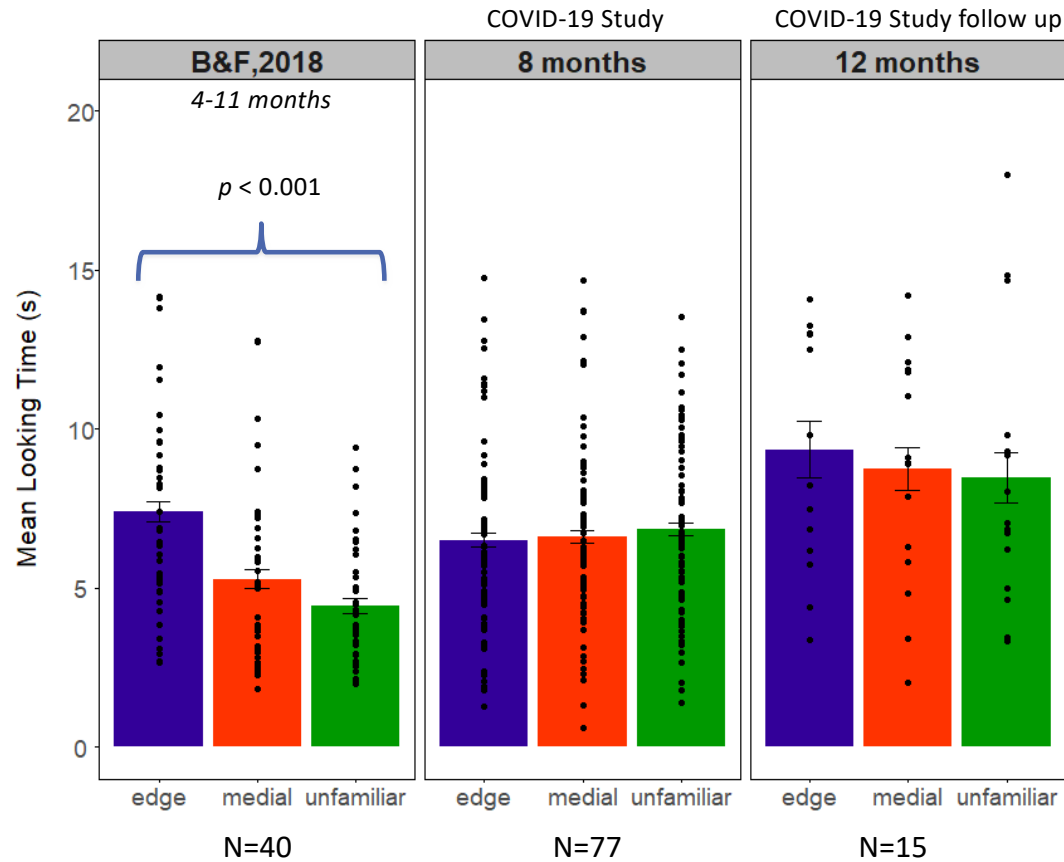

# Results

**Auditory Experiment (AUD)**

**Audiovisual Experiment (AV)**

# Results

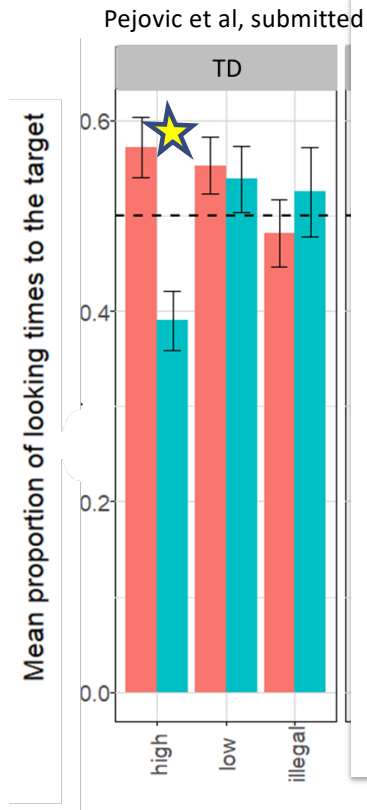

No word segmentation !

# Results

Sensitivity to phonotactic patterns in word learning, measured with eye-tracking (Frota et al., 2021, Pejovic et al., submitted)

N=31, mean age 20.4

N=20, mean age 20.4

**Training**  
■ labelled  
■ unlabelled

**No word learning !**

If preferred edge over medial (i.e., better at looking at the target in the word learning task)

Segmentation at 7-9 months and Word learning

# Results

Despite gains in vocabulary development with age, no convergence yet by 24 months

Infants from the COVID-19 study have **lower expressive vocabulary scores** than same age infants from the CDI-I norming study ( $p < .001$ ,  $Z = -2.9$ ,  $r = .23$ )

They scored **lower both for receptive** ( $p = .02$ ,  $Z = -2.24$ ,  $r = .18$ ) **and expressive vocabulary** ( $p = .03$ ,  $Z = -2.1$ ,  $r = .18$ ) than same age infants from the CDI-I norming study

They scored **lower both for receptive** ( $p = .01$ ,  $Z = -2.55$ ,  $r = .26$ ) **and expressive vocabulary** ( $p = .06$ ,  $Z = -1.84$ ,  $r = .19$ ) than same age infants from the CDI-I norming study

Infants from the COVID-19 study scored **lower for expressive vocabulary scores** ( $p = .04$ ,  $Z = -2.0$ ,  $r = .2$ ) than same age infants from the CDI-II norming study

12 months

N = 32, 11-13 mos, mean=12.6

15 months

N = 39, 14-16 mos, mean=15.3

18 months

N = 33, 17-19 mos, mean=18.2

24 months

N = 36, 24-25 mos, mean=24.2

---

# Discussion

1. Frota et al., (2022): No evidence for segmentation (not even at the prosodic edge)

- Presence/absence of the face mask
- Auditory only /audiovisual speech cues

- Audiovisual impact of face-masked speech was stronger than the auditory impact (some evidence towards a developing advantage of utterance-edge position without mask – see the published paper)

2. Follow up studies found a (prolonged) effect of exposure to altered speech cues and (other) COVID-related changes > Difference between pre-pandemic data and our findings

- **Segmentation abilities are delayed in infants from the COVID-19 study (12 months);**
- **At 20 months, they fail to use word learning mechanisms previously found at same age toddlers**
- **Delays in vocabulary development are still apparent at 24 months of age (CDI)**

# Discussion

Our results suggest an overall effect of the pandemic on early segmentation abilities and **later language development**, with significant delay patterns that persist until 24 months of age.

# Early Word Segmentation Behind the Mask
